Course Code: GEL472

#### 1 EXPERIMENT1 – INVERTING CIRCUIT:

To study the voltage shunt feedback in operational amplifier (Inverting mode Op-Amp).

**Aim:** To obtain the closed loop voltage gain

**Materials:** Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

100 K and 10 K, connecting wires, hookup wire, oscillator,

multimeter, digital voltmeter (DVM)

**Formula:** Closed loop voltage gain  $A_v = -\frac{R_f}{R_*}$ 

Where  $R_f$  is Feedback Resistor and

 $R_1$  is the input series resistor

**Procedure:** This experiment can be performed in two ways.

(a) Either by changing the values of feedback resistor ( $R_f$ ) and input resistor ( $R_1$ ) and keeping input signal voltage fixed or

(b) by keeping the  ${\cal R}_f$  and  ${\cal R}_1$  values fixed and changing amplitude of input signal.

In the first case—Make the connections as shown in below figure by selecting proper values of feedback and input resistors

| Title : | Lab Manual                 |      |   |
|---------|----------------------------|------|---|
| Doc#    | GEL472-LM-25               | Rev# | 0 |
| Page :  | Page <b>4</b> of <b>58</b> |      |   |
| -       |                            |      |   |

Course Code: GEL472

Connect the dual regulated power supply having ±15 V as shown in above figure.

Connect 10 K potentiometer between pin no. 1 and 5 (of Op-Amp 741) with its extreme ends and variable terminal of potentiometer to –Vcc.

Connect pin no. 2 and 3 (of Op-Amp 741) to the ground, and adjust the potentiometer resistance so that the output voltage should be zero. This arrangement is called offset null. Keep this position as it is throughout the experiment. Do not change the resistance of the potentiometer.

The input signal source Vi may be either DC or AC signal. Apply fixed input signal Vi from the Function Generator to the pin no. 2 of Op-Amp 741 through resistor  $R_1$ .

The pin no. 3 should be connected to ground terminal.

Preferably make the connections on breadboard so that the circuit can be assembled or de-assembled as per the requirement.

Select proper values of feedback resistor such as  $R_f =$  100 K and  $R_1 =$  10K.

Switch on power supply and apply a fixed input signal  $V_i$  =0.1 Vdc Note down the output voltage  $V_o$  by DVM in observation Table1.

For various values of  $R_f$  and  $R_1$  calculate theoretical and experimental gain and verify

| Sr. No | Resistors   | Input voltage (V) | Output voltage (V) | Voltage gain $A_{ m V} = -rac{V_0}{V_i}$ | Theoretical Voltage gain $A_{\rm V} = -\frac{R_{\rm f}}{R_{\rm l}}$ |
|--------|---|-------------------|--------------------|---|---|
| 1      | $R_{\rm f} = 100 \text{ K}$<br>$R_1 = 10 \text{ K}$ |                   |                    |   | -10   |
| 2      | $R_{\rm f} = 470 \text{ K}$<br>$R_1 = 47 \text{ K}$ |                   |                    |   | -10   |
| 3      | $R_{\rm f} = R_1 =$                                 |                   |                    |   |   |
| 4      | $R_{\rm f} = R_1 =$                                 |                   |                    |   |   |

| Title : | Lab Manual                 |      |   |
|---------|----------------------------|------|---|
| Doc#    | GEL472-LM-25               | Rev# | 0 |
| Page:   | Page <b>5</b> of <b>58</b> |      |   |

Course Code: GEL472

Second case—Make the connections as shown in the previous figure.

Connect  $R_f = 100 \text{ K}$  and  $R_1 = 10 \text{ K}$ .

Switch on the power supply.

Apply signal of fixed frequency or DC signal to the input terminal

Measure the corresponding output voltage by varying the amplitude of the input signal.

Note down the observations in Table 2.

Calculate the voltage gain  $A_{v}$ , and compare the theoretical gain with experimental gain.

| Sr. No. | Input voltage $V_i(V)$ | Output voltage $V_0$ ( $V$ ) | Voltage gain $A_{\rm V} = -\frac{V_0}{V_i}$ |
|---------|------------------------|------------------------------|---|
| 1       | 0.1                    |                              |   |
| 2       | 0.2                    |                              |   |
| 3       | 0.3                    |                              |   |
| 4       | 0.4                    |                              |   |
| 5       | 0.5                    |                              |   |
| 6       | 0.6                    |                              |   |
| 7       | 0.7                    |                              |   |
| 8       | 0.8                    |                              |   |
| 9       | 0.9                    |                              |   |

## Table2

#### **Results and Discussions:**

Theoretical and experimental gain were compared and were found to be identical. The output voltage is found to be negative which shows that there is 180° phase shift between input and output voltage

#### **Precautions:**

- Dual power supply must be regulated.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.

Course Code: GEL472

- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.
- Use proper values of Rf and R1.

## **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per table1 and Table2.

#### **VIVA Questions:**

- 1. What is called differential amplifier?
- 2. What are the typical characteristics of differential amplifier?
- 3. Why there is a need of two power supplies in differential amplifier?
- 4. What do you mean by single-ended and double-ended differential amplifier?
- 5. What are the properties of ideal Op-Amp?
- 6. List few applications of Op-Amp?
- 7. What do you mean by inverting and non-inverting mode of Op-Amp?
- 8. What is the gain of operational amplifier in inverting and non-inverting mode?

| Title : | Lab Manual                 |      |   |
|---------|----------------------------|------|---|
| Doc#    | GEL472-LM-25               | Rev# | 0 |

|         |                            |      |   |

Course Code: GEL472

#### 2 EXPERIMENT2 – NON INVERTING CIRCUIT:

To study the voltage series feedback in operational amplifier (Non-inverting mode Op-Amp)

**Aim:** To obtain the closed loop voltage gain

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

100 K and 10 K, connecting wires, hookup wire, oscillator,

multimeter, digital voltmeter (DVM)

Formula: Closed loop voltage gain  $A_v = 1 + \frac{R_f}{R_1}$ 

Where  $R_f$  is Feedback Resistor and

 $R_1$  is the input series resistor

**Procedure:** The procedure of this experiment is same as that of inverting

amplifier experiment no. 1. Instead of applying signal input to pin no. 2 of 741 Op-Amp, it is applied to pin no. 3. This experiment can also be performed in two ways as described in inverting amplifier

experiment.

The observation table is also similar, only theoretical voltage gain  $A_v=1+\frac{R_f}{R_1}$  should be mentioned, and accordingly the results should be written

| Title : | Lab Manual                 |      |   |
|---------|----------------------------|------|---|
| Doc#    | GEL472-LM-25               | Rev# | 0 |
| Page:   | Page <b>8</b> of <b>58</b> |      |   |
|         |                            |      |   |

Course Code: GEL472

#### **Results and Discussions:**

Theoretical and experimental gains were compared and were found to be identical. The output voltage is found to be positive which shows that there is no phase shift between input and output voltage. The voltage gain is always greater than one

#### **Precautions:**

- Dual power supply must be regulated.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.
- Use proper values of Rf and R1.

### **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information.

#### **VIVA Questions:**

- 1. What is the gain of differential amplifier in non-inverting mode?
- 2. On which factors the gain of Op-Amp depends?
- 3. Define input offset voltage and output offset voltage?
- 4. What is CMRR?
- 5. Define slew rate?
- 6. What will be the effect of slew rate on any application?
- 7. What is PSRR?
- 8. What do you know about temperature drift?

| Title : | Lab Manual                 |      |   |
|---------|----------------------------|------|---|
| Doc#    | GEL472-LM-25               | Rev# | 0 |
| Page:   | Page <b>9</b> of <b>58</b> |      |   |

Course Code: GEL472

## 3 EXPERIMENT3 – ADDER / SUBTRACTOR CIRCUITS:

To study operational amplifier as adder/subtractor

**Aim:** To add the given voltages and verify the result

To subtract the given voltages and verify the result

**Materials:** Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

100 K, 10 K, 1K Potentiometer, connecting wires, hookup wire,

Function generator, multimeter, digital voltmeter (DVM),

Oscilloscope.

Formula: For adder, output voltage  $V_0 = -(\frac{R_f}{R_o} \times V_1 + \frac{R_f}{R_b} \times V_2 + \frac{R_f}{R_c} \times V_3)$ 

If  $R_a = R_b = R_c = R_f = R$  then  $V_0 = -(V_1 + V_2 + V_3)$ 

Where  $\emph{V}_1$  ,  $\emph{V}_2$  and  $\emph{V}_3$  are the input voltages to be added, and  $\emph{V}_o$ 

is the output voltage

For subtractor, output voltage  $V_0 = -(V_2 - V_1)$ 

**Procedure:** Adder or summing and subtractor or difference inverting amplifier.

Make the connections as shown in below figures on breadboard. Use feedback resistor  $R_f$  and input resistors  $R_a=R_b=R_c=R_f=R=10K$ . The input voltages  $V_1$ ,  $V_2$  and  $V_3$  should be made variable using function generator and/or using voltage divider arrangement. Switch on the power supply, apply input voltage to

be added/subtracted (as the case may be), and note the

corresponding output voltage using DVM/oscilloscope. Record the

observations in observations table1 and table2

Course Code: GEL472

#### 4 EXPERIMENT4 – INTEGRATOR CIRCUIT:

Application of Op-Amp 741 as integrator

**Aim:** To study the Op-Amp as integrator

To observe the output waveform when square wave signal is

applied at input

Observe the change in output voltage when variable frequency

signal is applied at the input

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

multimeter, digital voltmeter (DVM), Oscilloscope.

**Formula:** Output voltage  $V_0 = \int \frac{1}{R \times C} V_i dt$ 

where  $V_i$  is the input signal voltage, R and C For subtractor, are the components connected in circuit as resistor and capacitor, selected as per  $T \leq R \times C$  required condition for integration

If  $V_i$  is a sinusoidal wave as  $V_i = V \sin \omega t$ 

Then  $V_0 = \int \frac{1}{R \times C} V \sin \omega t \, dt = \frac{1}{R \times C \times \omega} V \cos \omega t$ 

This Equation shows that the amplitude of the output signal is inversely proportional to the frequency of the input signal

The operating frequency  $f_a = \frac{1}{2\pi \times R_f \times C_f}$ 

The OdB frequency  $f_b = \frac{1}{2\pi \times R_1 \times C_f}$ 

**Procedure:** Make the connections as shown in below Figure 1 on bread board.

Select proper values of  $R_f$ ,  $R_1$  and  $C_f$  so that  $T \leq R_1 \times C_f$  is

satisfied.

By choosing proper value of  $C_f$ , calculate value of resistor  $R_1$  from  $f_b = \frac{1}{2\pi \times R_1 \times C_f}$ ,  $R_f$  is the resistor having high value, which provides feedback.  $f_b$  is the frequency below which the circuit can work as

practical integrator (Figure 2).

| Course C | ode: GEL472                 |      |   |

Connect the function generator at the input, and measure the amplitude of output signal keeping input signal amplitude constant for each frequency. Note down the output voltage for corresponding input frequency.

Draw the graph between output voltage against frequency. It should be observed that the amplitude of the output signal decreases with increasing frequency.

| -       |                                |                              |
| -       |                                |                              |
| -       |                                |                              |
| -       |                                |                              |

### **Results and Discussions:**

From the graph of output voltage against frequency it is observed that the output voltage decreases with increasing frequency. The square waveform is applied at the input, and output is observed which is ramp up and down, i.e. it generates the triangular wave. This shows that the circuit works as an integrator

#### **Precautions:**

- Dual power supply must be regulated.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.
- Selection of proper values of  $R_f$ ,  $R_1$  and  $C_f$  is necessary to satisfy  $T \le R_1 \times C_f$ , time period of the input cycle

## **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per table1.

### **VIVA Questions:**

- 1. How integrator circuit works?
- 2. Explain action of capacitor connected in feedback in integrator circuit.
- 3. What will be the output of integrator when sinusoidal wave is applied at input?
- 4. What are the characteristics of ideal operational amplifier?
- 5. Why is capacitor shunted by resistor in feedback?
- 6. Define slew rate?
- 7. Whether slew rate plays any role in integration? Explain

#### 5 **EXPERIMENT5 – DIFFERENTIATOR CIRCUIT:**

Application of Op-Amp 741 as differentiator

To study the Op-Amp as differentiator Aim:

Observe the change in output voltage when variable frequency

signal is applied at the input

Op-Amp 741, breadboard, regulated power supply ±15 V, resistors **Materials:** 

capacitors, connecting wires, hookup wire, Function generator,

multimeter, digital voltmeter (DVM), Oscilloscope.

Output voltage  $V_o = -R_f \times C_1 \times \frac{dV_i}{dt}$ Formula:

> where  $V_i$  is the input signal voltage,  $R_f$  is the resistance connected and  $C_1$  is the capacitor connected in Input. The negative sign indicates phase change of 180° between input and output signal. If a sinusoidal signal is applied at the input of the differentiator say

$$V_i = V \times \sin \omega t$$

The output will be  $V_0 = -R_f \times C_1 \times V \times \omega \times \cos \omega t$ 

This Equation shows that the amplitude of the output signal is proportional to the frequency of the input signal

At low frequencies the capacitive reactance is high resulting in low gain or low output of the differentiator, whereas at high frequencies the output voltage increases with frequencies of input signal.

**Procedure:** Make the connections as shown in below Figure 1 on bread board. Select proper of feedback resistor and capacitor as per the

frequency response of the differentiator so that time period of the

input signal  $T \geq R_f \times C_1$  is satisfied.

Calculate values of  $R_f$  and  $C_1$  from  $f_a = \frac{1}{2\pi \times R_f \times C_1}$  and  $f_b =$ 

 $f_b = 20 \times f_a$  and  $C_1 < 1\mu F$ . Satisfying  $R_1 \times C_1 = R_f \times C_f$ , evaluate values of  $R_1$  and  $C_f$ 

 $f_a$  is the frequency at which gain of the differentiator is 0 dB

## $f_b$ is the gain limiting frequency

The components  $R_1$  and  $C_f$  are used for stability of the circuit and high-frequency noise correction. By selecting value of  $f_a$  as highest frequency to be differentiated and assuming  $C_1>1\mu F$  calculate value of  $R_1$  and  $C_f$ 

Connect these components in circuit as shown below, and switch on the power supply. Apply sinusoidal input to the differentiator through the function generator. Keeping amplitude of the input sine wave constant, change the frequency, and note the corresponding output voltage. Record the readings in observation below Table and plot the graph between voltage gains against frequency. It should be observed that the output voltage increases with increasing frequency of the input signal.

#### **Results and Discussions:**

The frequency  $f_a$  (at which gain of the differentiator is 0 dB) and  $f_b$  (the gain limiting frequency) is calculated. The plot of gain against frequency of input signal is drawn which is linear and gain increases with frequency of input signal. Various waveforms such as sinusoidal, square and triangular are feed at the input of the differentiator, and output waveforms such as cosine, spikes and square are drawn

#### **Precautions:**

- Dual power supply must be regulated.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.
- Selection of proper values of R<sub>f</sub> and R<sub>1</sub>

## **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per above table.

#### **VIVA Questions:**

- 1. Explain working of differentiator
- 2.  $T \ge R_f \times C_1$  should be satisfied for working of differentiator, explain.
- 3. What will be the output of differentiator for sinusoidal waveform applied at input?
- 4. What are the different parameters of operational amplifier?
- 5. What is CMRR?

#### **6** EXPERIMENT6 – ACTIVE FILTERS:

To design and study active filters using Op-Amp

**Aim:** First-order low pass Butterworth filter

Second-order low pass Butterworth filter

First-order high pass Butterworth filter

Second-order high pass Butterworth filter

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

**Formula:** The Higher cut-off frequency:

 $f_H = \frac{1}{2\pi RC}$  first order low pass

 $f_H = \frac{1}{2\pi\sqrt{R_1}R_3C_1C_2}$  Second order low pass

The Lower cut-off frequency:

 $f_L = \frac{1}{2\pi RC}$  first order low pass

 $f_L = \frac{1}{2\pi\sqrt{R_1 R_3 C_1 C_2}}$  Second order low pass

**Procedure:** Initially design the filter circuit and calculate values of resistor R

and capacitor C. Select the higher cut-off frequency  $f_{\rm H}$ , value of capacitor C, and calculate the value of resistor R from the given

formula in first-order low pass Butterworth filter.

Similarly select the cut-off frequency  $f_H$  for second-order low pass filter, select the proper values of  $\mathcal{C}_1$  and  $\mathcal{C}_2$  capacitors, and calculate the values of  $\mathcal{R}_2$  and  $\mathcal{R}_3$  from the given formula.

Preferably choose the value of capacitor C less than 1  $\mu$ F.

The gain of the amplifier can be adjusted by proper selection of feedback resistor  $R_F$  and  $R_1$  as per our desired value of voltage

 $gain \left(1 + \frac{R_f}{R_1}\right).$ 

Make the connections as shown in below figures on breadboard, and apply  $\pm$  15V power supply to Op-Amp 741. Connect function generator to the input and Oscilloscope at the output. Change the

Course Code: GEL472

#### **Results and Discussions:**

The graph is plotted between voltage gains against frequency of the input signal, and cut-off frequency is calculated from the graph and formula. Both are found to be identical.

#### **Precautions:**

- Dual power supply must be regulated.
- All connections should be clean and tight.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Do not use operational amplifier in open loop condition.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.
- Selection of proper values of  $R_f$  and  $R_1$

#### **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per above table.

### **VIVA Questions:**

- 1. What do you mean by active filter?
- 2. What is the difference between active and passive filters?
- 3. What do you mean by cut-off frequency?
- 4. What is roll-off?
- 5. How roll-off is important in active filters?
- 6. What is the difference between digital and analog filters?
- 7. What is first-order and second- order Butterworth filter?

## 7 EXPERIMENT7 – BAND PASS AND BANS STOP FILTERS:

To design and study active band pass and band stop or notch filter

**Aim:** Design of active band pass filter and study frequency response

Design of active band stop or notch filter and study the frequency

response

**Materials:** Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

Formula: Band Pass Filter:

 $f_C = \sqrt{f_H f_L}$  Center Frequency

 $Q = \frac{f_C}{f_H f_L}$  Quality Factor

Where  $f_{\mathcal{C}}$  is called center frequency,  $f_{\mathcal{H}}$  is higher cut-off and

 $f_L$  is the lower cut-off frequency

 $BW = f_H - f_L \text{ is the band Width}$ 

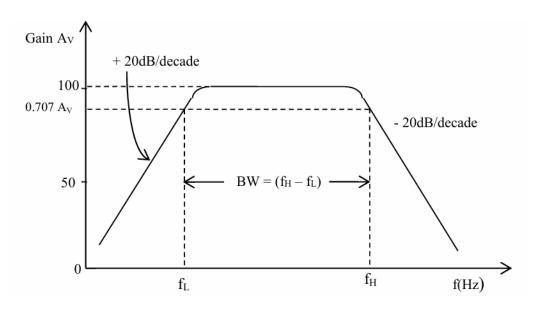

Figure1 – Frequency response of first order band pass filter

| Title : | Lab Manual                  |      |   |

Course Code: GEL472

## Band stop or Notch Filter:

The same formula for centre frequency and bandwidth is used for wide band stop filter, but for narrow band reject filter, the frequency at which maximum attenuation occurs is called notch frequency  $f_N$ , which is given by

$$f_N = \frac{1}{2 \pi R C}$$

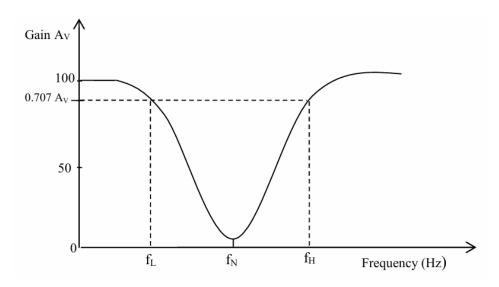

Figure2 – Frequency response of Notch filter

### **Procedure:**

By cascading high pass and low pass filters together a band pass filter can be formed.

Make the connection as shown in below figures for respective filters on breadboard. In case of band pass filter for obtaining ±20 dB band pass, cascade first-order high pass and first order low pass filters. To obtain ±40 dB band pass, cascade second-order high pass and second order low pass filters in series. Design filter circuit with proper component values of R and C

| 7       |                                |                          |                                  |

#### **Results and Discussions:**

#### (a) Band pass filter:

The band pass filter is designed by considering higher cut-off  $(f_H)$  = \_\_\_\_\_ KHz and lower cut-off  $(f_L)$  = \_\_\_\_\_ KHz frequencies. Proper values of resistors and capacitors are connected in the filter circuit. The frequency response is studied, and  $f_H$  and  $f_L$  values are evaluated from the graph of voltage gain versus frequency plot. Also bandwidth is calculated as  $(f_H - f_L)$  which is found to be \_\_\_\_\_\_ KHz. The quality factor is found to be \_\_\_\_\_\_ . It is found that the values of  $f_H$  and  $f_L$  match with the theoretical values evaluated from formula, which were predefined.

#### (b) Band stop or Twin-T notch filter

The pass band and the stop band of frequencies are determined. Also notch frequency is calculated from the graph of voltage gain versus frequency plot. The notch frequency  $(f_N)$  evaluated from the graph and the predefined  $f_N$  from formula are found to be identical

#### **Precautions:**

- Dual power supply must be regulated.
- All connections should be clean and tight.

## 8 EXPERIMENTS – VOLTAGE TO CURRENT & CURRENT TO VOLTAGE CONVERTERS:

Study of Op-Amp as voltage to current converter and current to voltage converter

**Aim:** (i) Voltage to current converter

(ii) Current to voltage converter

**Materials:** Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

**Formula:** (i) Voltage to current converter:

$$I_{Out} = \frac{V_i}{R}$$

(ii) Current to voltage converter:

$$V_O = V_i \times R$$

**Procedure:** 

Make the connections as shown in below Figs. Switch on the power supply. Vary input in the circuits. Note down the input voltage and corresponding output current in case of voltage to current converter, and note down the current (I) and the output voltage in case of current to voltage converter. Record the observations in observation table. Plot the graph between voltage and current in case of V to I converter and current versus voltage in case of I to V converter

|         |                             |      |   |

Course Code: GEL472

#### **Results and Discussions:**

As we change the input voltage, the output current will also change, and it is directly proportional. The V-I plot is linear.

Similarly change in the input current will change output voltage, and I-V plot is linear. The input current is directly proportional to output voltage  $V_{\mathcal{O}}$ 

#### **Precautions:**

- Dual power supply must be regulated.
- All connections should be clean and tight.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.

#### **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per above table.

- 1. What is voltage to current converter?
- 2. What are the applications of voltage to current converter?
- 3. Explain working of current to voltage converter?

#### 9 EXPERIMENT9 – PRECISION RECYIFIER AND PEAK DETECTOR:

Study of operational amplifier as precision rectifier and peak detector

Aim: (i) Half wave rectifier

(ii) Peak detector

**Materials:** Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

**Procedure:** Precision rectifiers rectify very small AC voltage using Op-Amp.

Make the connections as shown in below Figs. Switch on the power supply, apply very small AC signal say 20 mV of 1 KHz frequency to the rectifiers/detector, and observe the output on the oscilloscope.

Measure the output voltage using DMM. Record the output voltages for 30, 40, 50, 60....... 100 mV up to 1 V, and note down corresponding output in observation table. Trace the input waveform as well as output waveform in both experiments.

| _       | 100 mV                     |                          |

### **Results and Discussions:**

In ordinary rectifier sufficient input voltage is required to conduct the diode. Small magnitude AC signals cannot be rectified by ordinary diode alone. But if it is used in active rectifier circuits then very small AC signals can be rectified or detected.

#### **10 EXPERIMENT10 – PHASE SHIFT OSCILLATOR:**

Design and study of operational amplifier as phase shift oscillator

Aim: (i) Design phase shift oscillator

(ii) Measure frequency of output signal

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

Formula: (i) Voltage Gain:

$$A_V = \lfloor \frac{R_f}{R_1} \rfloor$$

(ii) Frequency of oscillation:

$$f_o = \frac{1}{2\pi\sqrt{6}RC}$$

**Procedure:** 

Make the connections as shown in below Fig. Select frequency of oscillator  $f_o$  and value of capacitor C, and then calculate value of resistor R from the given formula  $f_o = \frac{1}{2\pi\sqrt{6}RC}$ . Maintain the gain of the amplifier as  $R_f = 29~R_1$  by selection. Generally, 1MOhm potentiometer is used. Connect oscilloscope at the output to observe the waveform. Switch on the power supply and adjust the voltage gain of the amplifier to 29 by adjusting the potentiometer resistance to  $29~R_1$ , so that oscillation can start. Calculate the frequency of oscillation from Oscilloscope by measuring the time of the cycle. Note down the reading in the observation table. Verify the experimental frequency with the selected frequency  $f_o$  of oscillation. Repeat this experiment for various values of R or C combination and verify the frequency of oscillation.

#### **Observation Table:**

| Sr.<br>No. | Value of<br>resistor<br>(KΩ) | Value of capacitor (μF) | Experimental frequency<br>observed on CRO (KHz) | Frequency selected from formula $f_0$ (KHz) |
|------------|------------------------------|-------------------------|---|---|
| 1          |                              |                         |   |   |
| 2          |                              |                         |   |   |
| 3          |                              |                         |   |   |
| 4          |                              |                         |   |   |
| 5          |                              |                         |   |   |

### **Results and Discussions:**

The phase shift oscillator is designed, and waveform is observed on Oscilloscope which is sinusoidal. The frequency is calculated from Oscilloscope by measuring the time of the cycle. The value of frequency of oscillation  $f_o$  is verified with the theoretical value selected initially. It is found that both frequencies are identical

#### **Precautions:**

- As feedback is small, starting oscillations is difficult
- The output is also small

#### 11 EXPERIMENT11 – WIEN BRIDGE OSCILLATOR:

To design and construct the Wien bridge oscillator using Op-Amp

Aim: (i) To design Wien bridge oscillator

(ii) To measure the frequency of output signal

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

**Formula:** (i) Voltage gain of the non-inverting amplifier is given by:

$$A_V = 1 + \frac{R_f}{R_1} = 3$$
 or  $R_f = 2R_1$ 

(ii) Frequency of oscillation:

$$f_o = \frac{1}{2\pi RC}$$

**Procedure:** Experimental procedure is same as given in phase shift oscillator

experiment no. 10

Course Code: GEL472

#### **Observation Table:**

| Sr.<br>No. | Value of resistor (KΩ) | Value of capacitor (µF) | Experimental frequency observed on CRO (KHz) | Frequency selected from formula $f_0$ (KHz) |
|------------|------------------------|-------------------------|--|---|
| 1          |                        |                         |  |   |
| 2          |                        |                         |  |   |
| 3          |                        |                         |  |   |
| 4          |                        |                         |  |   |
| 5          |                        |                         |  |   |

#### **Results and Discussions:**

The Wien Bridge oscillator is designed, and waveform is observed on Oscilloscope. The frequency is calculated from Oscilloscope by measuring the time of the cycle. The value of frequency of oscillation  $f_o$  is verified with the theoretical value selected initially. It is found that both frequencies are identical

#### **Precautions:**

- Wien bridge oscillator offers zero phase shift, and hence non-inverting mode of Op-Amp is preferred
- While resonating the voltages at non-inverting and inverting terminals should be equal and in phase with each other
- Gain should be greater than 3 to start the oscillation
- There is a frequency limit of 1 MHz
- Dual power supply must be regulated.
- All connections should be clean and tight.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Do not operate operational amplifier under open loop condition; otherwise it will go into saturation
- Measure all voltages with respect to ground.

### 12 EXPERIMENT12 – SQUARE WAVE GENERATOR:

Design and study of astable multivibrator using Op-Amp (Square wave generator)

Aim: (i) Design of a stable multivibrator

(ii) Measure on and off time of the square wave

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

Formula: Frequency of oscillator:

$$f = \frac{1}{2RC} = \frac{1}{T}$$

Where T is time of one cycle

$$T = T_{ON} + T_{OFF}$$

**Procedure:** 

The astable multivibrator is called free-running multivibrator or square wave generator. The resistor R and capacitor C decide the frequency of oscillation. For proper oscillations the potentiometer of 22 Kohm is used. By adjusting the value of resistor, the proper feedback is provided. Make the connections as shown in below Fig. Switch on the power supply, and adjust the resistance  $R_1$  to get the proper feedback so that oscillations will be produced at the output. Connect the oscilloscope at the output, and observe the square wave generated. Measure on and off time of the pulse, and calculate the frequency of oscillation. Record the observations in observation table. Change R and C values or any one component will change the frequency of oscillation. Perform this experiment for various values of R and C, and record the observation for calculation of frequency.

| 4          |                                 |                                 |                          |                               |                   |                |
| 5          |                                 |                                 |                          |                               |                   |                |

#### **Results and Discussions:**

The square wave is observed on the oscilloscope, and on and off time are measured. Frequency of oscillation of the wave form is found to be\_\_\_\_\_Hz. By changing the R and C values experiment is repeated.

### **Precautions:**

- Adjust value of R1 to get proper feedback
- Dual power supply must be regulated.
- All connections should be clean and tight.

Course Code: GEL472

- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.

#### **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per above table.

- 1. What are non-sinusoidal oscillators?
- 2. How square wave is generated?
- 3. What do you mean by symmetrical and unsymmetrical multivibrators?
- 4. Describe working of a stable multivibrator in brief

#### 13 EXPERIMENT13 – TRIANGULAR WAVE GENERATOR:

Design and study of triangular wave generator using Op-Amp

**Aim:** (i) Design of triangular waveform generator

(ii) Measure the frequency of the oscillations

Materials: Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

Formula: Frequency of oscillator:

$$f = \frac{R_3}{4R_1C_1R_2}$$

**Procedure:** 

Make the connections as shown in below Fig. Connect proper values of  $R_1$ ,  $R_2$ ,  $R_3$  and  $C_1$  in the circuit. Switch on the power supply. Connect the oscilloscope at the output to observe the waveform. The first Op-Amp will act as comparator, i.e. zero crossing detector because inverting terminal of the Op-Amp is connected to ground. Second Op-Amp acts as integrator which converts square wave into triangular waveform. Adjust the resistance of the potentiometer  $R_3$  to get square wave output at the first Op-Amp. The frequency of oscillations can be adjusted by changing the value of  $R_3$ . Record the observations for various values of  $R_3$  in observation table, and calculate the frequency of oscillations f.

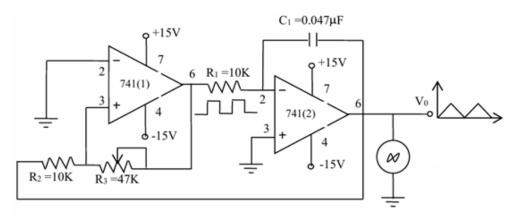

Figure1 - Triangular waveform generator

| Title : | Lab Manual                  |      |   |
|---------|-----------------------------|------|---|
| Doc#    | GEL472-LM-25                | Rev# | 0 |
| Page:   | Page <b>53</b> of <b>58</b> |      |   |
|         |                             |      |   |

Course Code: GEL472

NOTE: If the on time of the square wave is adjusted to be small, the oscillator will work as sawtooth waveform generator. Rest of the procedure and experiment is same as triangular waveform generator.

#### **Observation Table:**

| Sr.<br>No. | Resistor values (KΩ) |       | ues   | Value of capacitor C (μF) | Frequency f (Hz) from formula | Frequency measured on CRO (Hz) |
|------------|----------------------|-------|-------|---------------------------|-------------------------------|--------------------------------|
|            | $R_1$                | $R_2$ | $R_3$ |                           |                               |                                |
| 1          |                      |       |       |                           |                               |                                |
| 2          |                      |       |       |                           |                               |                                |
| 3          |                      |       |       |                           |                               |                                |
| 4          |                      |       |       |                           |                               |                                |
| 5          |                      |       |       |                           |                               |                                |
| 6          |                      |       |       |                           |                               |                                |

#### **Results and Discussions:**

By changing the values of  $R_1$ ,  $R_2$  and  $R_3$  the frequency of oscillation is changed. The frequency calculated from formula and measured frequency on Oscilloscope are found to be identical.

#### **Precautions:**

- Measure accurate time period of cycle on oscilloscope
- Select proper values of resistors and capacitors
- To start the oscillations adjust value of  $R_3$
- Dual power supply must be regulated.
- All connections should be clean and tight.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.

|         |                             |      |   |

Course Code: GEL472

### **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per above table.

- 1. How integrator converts square wave into triangular wave?
- 2. What is the necessity of adjusting the resistor value of  $R_3$ ?
- 3. Explain the working of comparator
- 4. What is duty cycle?
- 5. What will be the effect of change in duty cycle on output waveform?
- 6. Explain working of integrator
- 7. How ramp up and ramp down voltage is generated?
- 8. List the factors which decide the frequency of oscillation of triangular wave

### 14 EXPERIMENT14 – FREQUENCY TO VOLTAGE CONVERTER:

To study the frequency to voltage (F/V) converter using Op-Amp

**Aim:** (i) Design and construct the F/V converter

(ii) Calculate the change in output with input frequency change

**Materials:** Op-Amp 741, breadboard, regulated power supply ±15 V, resistors

capacitors, connecting wires, hookup wire, Function generator,

digital Multimeter (DMM), Oscilloscope.

**Procedure:** The first stage Op-Amp is working as Schmitt trigger and second

stage as integrator. The sinusoidal wave is converted into square waveform by the Schmitt trigger, and integrator produces a ramp. Make the connections as shown in below Fig. The oscillator is connected at the input, and the sinusoidal signal is directly connected to the inverting terminal of the first stage Op-Amp. Change the frequency of the input signal and adjust the amplitude

to get square wave output of the Schmitt trigger. Note down the output voltage for corresponding input signal frequency. Record the observations in observation table. Plot the graph between input signal frequency and output voltage. A linear plot will give

you change in output voltage per frequency of input signal.

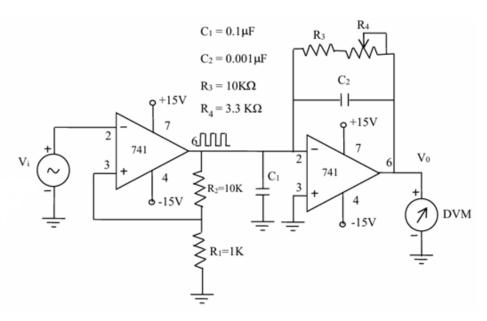

Figure1 – Frequency to voltage converter

Course Code: GEL472

### **Observation Table:**

| $V_i =$ |  | V | 7 |
|---------|--|---|---|
|---------|--|---|---|

| Sr. No. | Frequency of input signal (Hz) | Output voltage $V_0$ (V) |
|---------|--------------------------------|--------------------------|
| 1       |                                |                          |
| 2       |                                |                          |
| 3       |                                |                          |
| 4       |                                |                          |
| 5       |                                |                          |
| 6       |                                |                          |

#### **Results and Discussions:**

The output voltage varies linearly with increasing frequency of the input signal. The change in output voltage with change in input frequency of the signal is found to be \_\_\_\_\_.

#### **Precautions:**

- Dual power supply must be regulated.
- All connections should be clean and tight.
- Apply very small input voltage so that the Op-Amp should not be saturated, because of the restrictions of amplifier that the amplified output should not go beyond supply voltage.
- Measure all voltages with respect to ground.
- Use high input impedance voltmeter for voltage measurement to avoid the loading.

#### **Software Implementation:**

Draw the circuit on Multisim CAD and apply the same steps conducted in above experimentation and fill the information as per above table.

### **15 APPENDIX:**

The IC 741 is an operational amplifier designed by Fair Child semiconductors.

It is a versatile amplifier used as a multipurpose device in many electronic instruments/equipments.

The pin configuration of this amplifier is given in below figures:
